

**Representing small scale runoff
generation and sub-surface flow patterns,
induced by micro-topography, on a
coarser grid using superficial rill storage
height variations.**

Sven Frei & Jan H. Fleckenstein

sven.frei@uni-bayreuth.de; Department of Hydrology, University of Bayreuth

BACKGROUND

Lehstenbach Catchment:

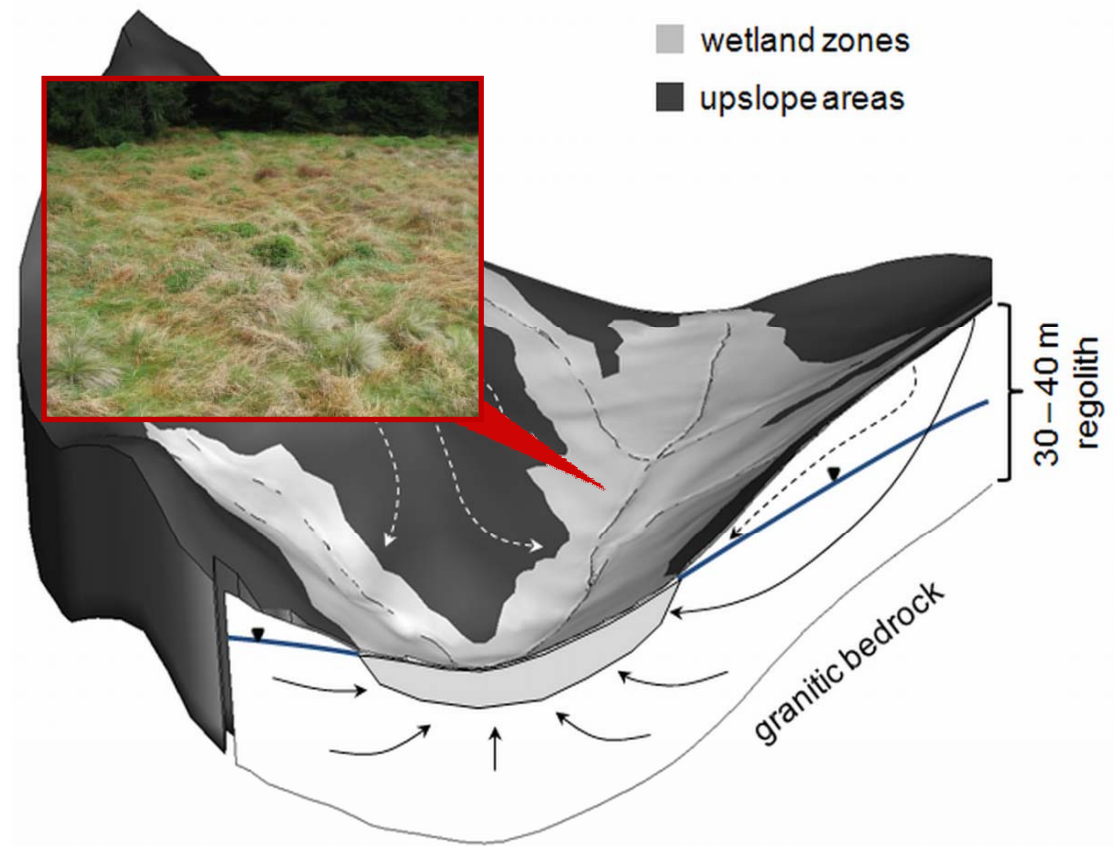

- ~4.2 km²; located in North-Eastern Bavaria
- 1/3 of area: riparian wetlands
- areas controll event runoff generation & water quality
- wetlands show pronounced micro-topographical structures (*hollow* & *hummock* sequences)

influence of micro-topography on

- ✓ runoff generation
- ✓ subsurface flow patterns
- ✓ biogeochemical settings

HGS
modeling studies

EVENT - RUNOFF GENERATION

Bayceer

Bayreuth Center of Ecology
and Environmental Research

simulated

high flow → dominated by surface runoff

Effects of micro-topography on surface-subsurface exchange and runoff generation in a virtual riparian wetland – A modeling study

SUBSURFACE RESIDENCE TIMES

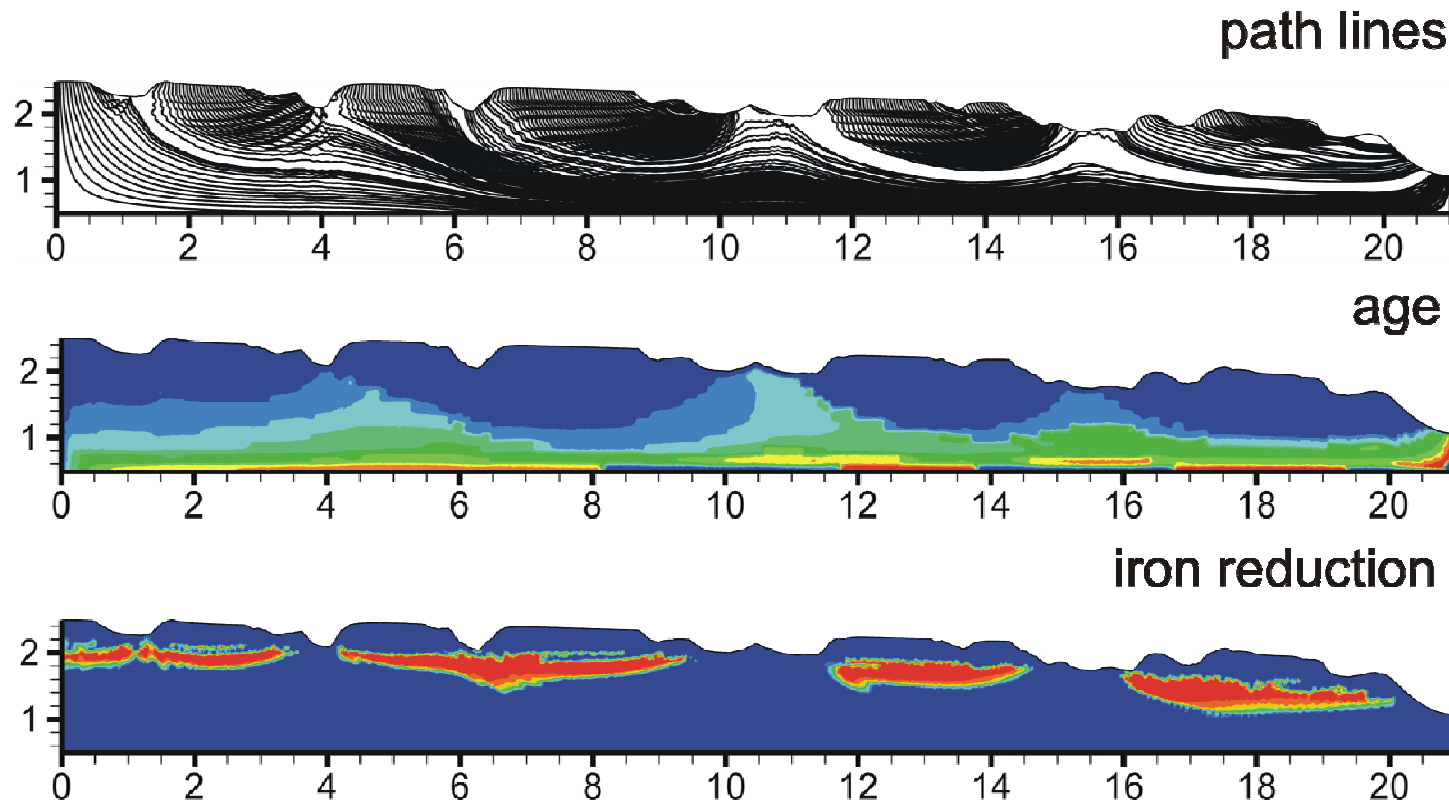

micro-topography → power law distributed RT

article in preperation

HOT SPOT FORMATION

Bayceer

Bayreuth Center of Ecology
and Environmental Research

micro-topography → formation of biogeochemical hot spots

article in preperation

PROBLEM

complex subsurface flow

variably saturated flow

integrated surface runoff

complex surface runoff
(surface flow networks)

high grid resolution
(231.000 nodes)

+

non-parallel version of HGS

extremely long computation times
(48 days for a yearly simulation)

How to speed it up???

reduction of grid resolution without losing too much process complexity

→ rep. micro-topography by superficial rill storage height variations

RILL / DEPRESSION STORAGE

Definition (HGS Manual):

It represents the amount of storage that must be filled before any lateral surface flow can occur. Microtopographic relief, relative to the scale of the finite elements in the grid, is included in rill storage and can have a substantial impact on hydrograph shape [Woolhiser *et al.*, 1997].

$h_o \leq H_o \rightarrow$ no lateral surface flow

\rightarrow implemented within HGS to account for *surface flow retention* due to micro-topography and/or vegetation

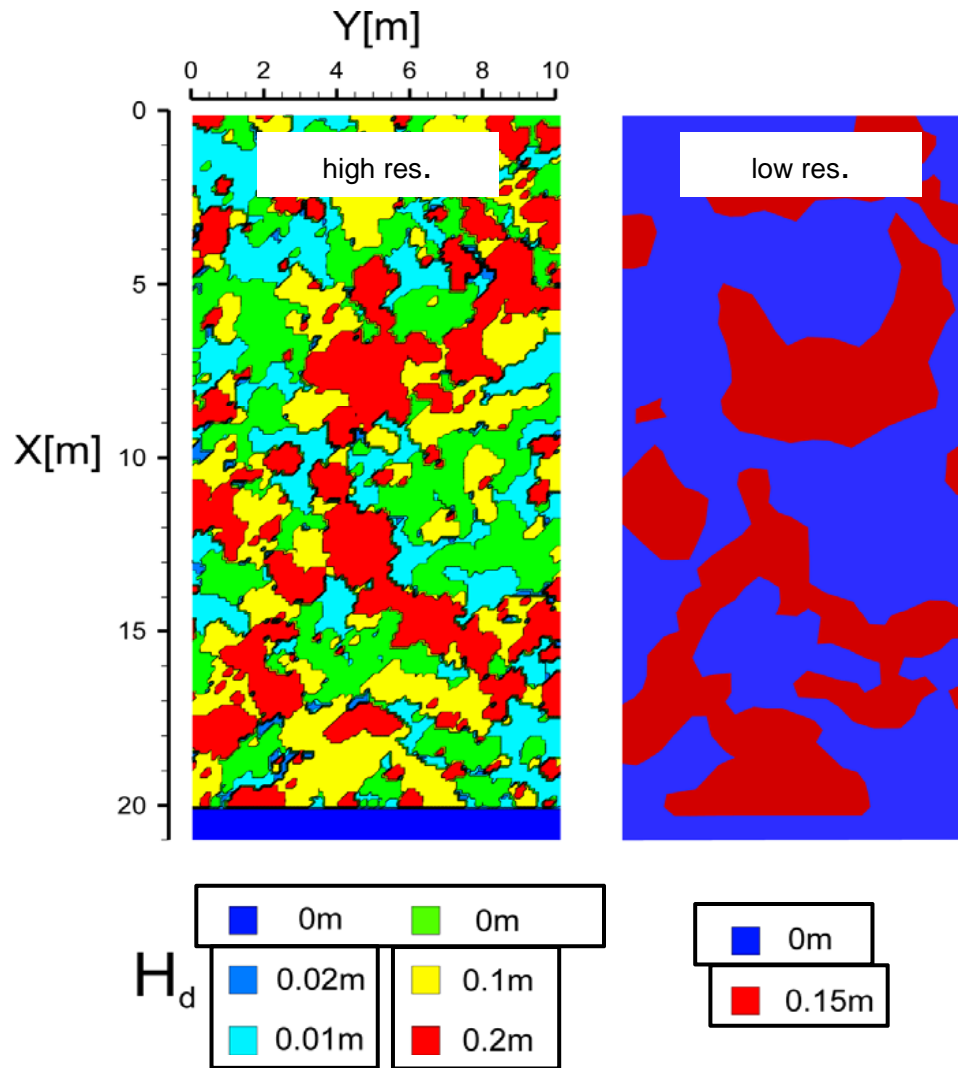

$h_o > H_o \rightarrow$ lateral surface flow

H_d : rill storage height [L]

h_o : ponded water depth [L]

SUPERFICIAL RILL STORAGE VARIATIONS

hummocks → NO surface runoff

Two different models:

- 1) high resolution + rill storage variation
(231.000 nodes; planar)
- 2) low resolution + rill storage variation
(20.900 nodes; planar)

VS.

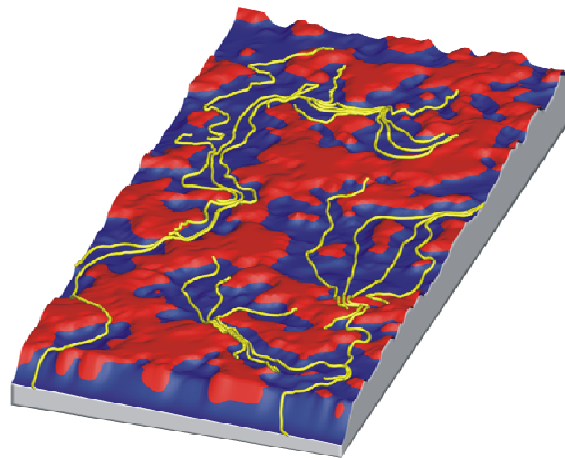

- original micro-topography model
(231.000 nodes; 3D micro-topo)
- planar reference
(231.000 nodes; planar without
rill storage variation)
